## Cryptosystem

A cryptosystem is a five-tuple $(\boldsymbol{P}, \boldsymbol{C}, \boldsymbol{K}, \boldsymbol{E}, \boldsymbol{D})$, where the following conditions are satisfied:

1. $\boldsymbol{P}$ is a finite set of possible plaintexts
2. $\boldsymbol{C}$ is a finite set of possible cipher-texts
3. $\boldsymbol{K}$, the key-space, is a finite set of possible keys
4. For each $K \in K$, there is an encryption rule $e_{K} \in E$ and a corresponding decryption rule $d_{K} \in D$. Each $e_{K}: \boldsymbol{P} \rightarrow \boldsymbol{C}$ and $d_{K}: \boldsymbol{C} \rightarrow \boldsymbol{P}$ are functions such that $d_{K}\left(e_{K}(x)\right)=x$ for every plaintext $x \in P$.

The Communication Channel
2010/07/23
Wireless Communication Engineering 1

Let $P=C=Z_{26} . K$ consists of all possible permutations of the 26 symbols $0,1, \ldots, 25$. For each permutation $\pi \in K$, define

$$
e_{\pi}(x)=\pi(x),
$$

and define

$$
d_{\pi}(y)=\pi^{-1}(y)
$$

where $\pi^{-1}$ is the inverse permutation to $\pi$.

## Shannon's Theory

- Computational Security (RSA, etc.)
- Unconditional Security (based on Shannon Information Theory)

Suppose $\mathbf{X}$ and $\mathbf{Y}$ are random variables. We denote the probability that $\mathbf{X}$ takes on the value $x$ by $p(x)$, and the probability that $\mathbf{Y}$ takes on the value $y$ by $p(y)$. The joint probability $p(x, y)$ is the probability that $\mathbf{X}$ takes on the value $x$ and $\mathbf{Y}$ takes on the value $y$.

The conditional probability $p(x \mid y)$ denotes the probability that $\mathbf{X}$ takes on the value $x$ given that $\mathbf{Y}$ takes on the value $y$. The random variables $\mathbf{X}$ and $\mathbf{Y}$ are said to be independent if $p(x, y)=p(x) p(y)$ for all possible values $x$ of $\mathbf{X}$ and $y$ of $\mathbf{Y}$.

Joint probability can be related to conditional probability by the formula

$$
p(x, y)=p(x \mid y) p(y)
$$

Interchanging $x$ and $y$, we have that

$$
p(x, y)=p(y \mid x) p(x) .
$$

[^0]Wireless Communication Engineering

From these two expressions, we immediately obtain the following result, which is known as Bayes'
Theorem.

Bayes' Theorem
If $p(y)>0$, then

$$
p(x \mid y)=\frac{p(x) p(y \mid x)}{p(y)} .
$$

## Spurious Keys and Unicity Distance

Let $(\boldsymbol{P}, \boldsymbol{C}, \boldsymbol{K}, \boldsymbol{E}, \boldsymbol{D})$ be a cryptosystem. Then

$$
H(\mathbf{K} \mid \mathbf{C})=H(\mathbf{K})+H(\mathbf{p})-H(\mathbf{C})
$$

First, observe that $H(\mathbf{K}, \mathbf{P}, \mathbf{C})=H(\mathbf{C} \mid \mathbf{K}, \mathbf{P})+H(\mathbf{K}, \mathbf{P})$.
Now, the key and plaintext determine the ciphertext uniquely, since $y=e_{K}(x)$.
This implies that $H(\mathbf{C} \mid \mathbf{K}, \mathbf{P})=0$. Hence,
$H(\mathbf{K}, \mathbf{P}, \mathbf{C})=H(\mathbf{K}, \mathbf{P})$. But $\mathbf{K}$ and $\mathbf{P}$ are independent, so $H(\mathbf{K}, \mathbf{P})=H(\mathbf{K})+H(\mathbf{P})$. Hence,

$$
H(\mathbf{K}, \mathbf{P}, \mathbf{C})=H(\mathbf{K}, \mathbf{P})=H(\mathbf{K})+H(\mathbf{P})
$$

2010/07/23
Wireless Communication Engineering I

## Entropy of a natural language

Suppose $L$ is a natural language.
The entropy of $L$ is defined to be the quantity

$$
H_{L}=\lim _{n \rightarrow \infty} \frac{H\left(\mathbf{P}^{n}\right)}{n}
$$

and the redundancy of $L$ is defined to be

$$
R_{L}=1-\frac{H_{L}}{\log _{2}|P|}
$$

## Unicity distance

The unicity distance of a cryptosystem is defined to be the value of $n$, denoted by $n_{0}$, at which the expected number of spurious keys becomes zero; i.e., the average amount of ciphertext required for an opponent to be able to uniquely compute the key, given enough computing time.

$$
n_{0} \approx \frac{\log _{2}|K|}{R_{L} \log _{2}|P|}
$$

## DES

1. Given a plaintext $x$, a bit-string $x_{0}$ is constructed by permuting the bits of $x$ according to a (fixed) initial permutation IP. We write $x_{0}=\operatorname{IP}(x)=L_{0} R_{0}$, where $L_{0}$ comprises the first 32 bits of $x_{0}$ and $R_{0}$ the last 32 bits.
2. 16 iterations of a certain function are then computed. We compute $L_{i} R_{i}, 1 \leq i \leq 16$, according to the following rule:

$$
\begin{aligned}
L_{i} & =R_{i-1} \\
R_{i} & =L_{i-1} \oplus f\left(R_{i-1}, K_{i}\right)
\end{aligned}
$$

One round of DES encryption

Wireless Communication Engineering I

ElGamal Cryptosystem and Discrete Logs

## Problem Instance

$I=(p, \alpha, \beta)$, where $p$ is prime, $\alpha \in \mathrm{Z}_{p}$ is a primitive element, and $\beta \in \mathrm{Z}_{p}{ }^{*}$.

Objective
Find the unique integer $a, 0 \leq a \leq p-2$ such that

$$
\alpha^{a} \equiv \beta(\bmod p)
$$

We will denote this integer $a$ by $\log _{\alpha} \beta$.
2010/07/23
Wireless Communication Engineering

Let $p$ be a prime such that the discrete $\log$ problem in $Z_{p}$ is intractable, and let $\alpha \in \mathrm{Z}_{p}{ }^{*}$ be a primitive element.
Let $P=\mathrm{Z}_{p}{ }^{*}, C=\mathrm{Z}_{p}{ }^{*} \times \mathrm{Z}_{p}{ }^{*}$, and define

$$
K=\left\{(p, \alpha, a, \beta): \beta \equiv \alpha^{a}(\bmod p)\right\}
$$

The values $p, \alpha$ and $\beta$ are public, and $a$ is secret.
For $K=(p, \alpha, a, \beta)$, and for a (secret) random number $k \in \mathrm{Z}_{p-1}$, define

$$
e_{K}(x, k)=\left(y_{1}, y_{2}\right)
$$

2010/07/23
Wireless Communication Engineering

Let $G$ be a generating matrix for an $[n, k, d]$ Goppa code $\mathbf{C}$, where $n=2^{m}, d=2 t+1$ and $k=n-m t$. Let $S$ be a matrix that is invertible over $Z_{2}$, let $P$ be $n \times n$ an permutation matrix, and let $G^{\prime}=S G P$. Let $\boldsymbol{P}=\left(\mathrm{Z}_{2}\right)^{k}, \boldsymbol{C}=\left(\mathrm{Z}_{2}\right)^{n}$, and let

$$
K=\left\{\left(G, S, P, G^{\prime}\right)\right\}
$$

where $G, S, P$, and $G^{\prime}$ are constructed as described above.
$G^{\prime}$ is public, and $G, S$, and $P$ are secret.
For $K=\left(G, S, P, G^{\prime}\right)$, define $e_{K}(\mathbf{x}, \mathbf{e})=\mathbf{x} G^{\prime}+\mathbf{e}$

## McEliece Cryptosystem

2010/07/23
Wireless Communication Engineering 1
where

$$
y_{1}=\alpha^{k} \bmod p
$$

and

$$
y_{2}=x \beta^{k} \bmod p
$$

For $y_{1}, y_{2} \in Z_{p}{ }^{*}$, define

$$
d_{K}\left(y_{1}, y_{2}\right)=y_{2}\left(y_{1}{ }^{a}\right)^{-1} \bmod p
$$

2010/07/23 Wireless Communication Engineering I

## where $\mathbf{e} \in\left(Z_{2}\right)^{n}$ is a random vector of weight $t$.

Bob decrypts a ciphertext $\mathbf{y} \in\left(\mathrm{Z}_{2}\right)^{n}$ by means of the following operations:

```
1. Compute \(\mathbf{y}_{1}=\mathbf{y} P^{-1}\).
2. Decode \(\mathbf{y}_{1}\), obtaining \(\mathbf{y}_{1}=\mathbf{x}_{1}+\mathbf{e}_{1}\), where \(\mathbf{x}_{1} \in \mathbf{C}\).
3. Compute \(\mathbf{x}_{0} \in\left(\mathbf{Z}_{2}\right)^{k}\) such that \(\mathbf{x}_{0} G=\mathbf{x}_{1}\).
4. Compute \(\mathbf{x}=\mathbf{x}_{0} S^{-1}\).
```

## Signature Schemes

A signature scheme is a five-tuple $(\boldsymbol{P}, \boldsymbol{A}, \boldsymbol{K}, \boldsymbol{S}, \boldsymbol{V})$, where the following conditions are satisfied:

1. $\boldsymbol{P}$ is a finite set of possible messages
2. $\boldsymbol{A}$ is a finite set of possible signatures
3. $\boldsymbol{K}$, the key-space, is a finite set of possible keys
4. For each $K \in K$, there is a signing algorithm $\operatorname{sig}_{K} \in S$ and a corresponding verification algorithm ver $_{K} \in V$. Each $\operatorname{sig}_{K}: \boldsymbol{P} \rightarrow \boldsymbol{A}$ and ver $_{K}: P \times A \xrightarrow{\text { \{ true, false }\} \text { are functions such that }}$ the following equation is satisfied for every message $x \in P$ and for every signature $y \in A$

$$
\operatorname{ver}(x, y)=\left\{\begin{array}{lll}
\text { true } & \text { if } & y=\operatorname{sig}(x) \\
\text { false } & \text { if } & y \neq \operatorname{sig}(x)
\end{array}\right.
$$

2010/07/23

- Correlation between the key and operationis isused intipher text \(c\)

- DPA(Differential Power Analysis): Observe the internal data

\section*{Data hamming weight and power consumption}

\section*{Protection against power analysis}
- Protect SPA: Perform the constant operation pattern

Processing time increased \(+33 \%\) for dummy operation
Protect DPA: Randomize the internal data to hide the correlation
Without protection With protection: randomize the data

Problem: processing time overhead is increased with protection

\section*{Set up}

Measuring Power Consumption

Hamming Weight or Hamming Distance Leakage

Power consumption grows in proportion with the hamming weight of the data (for certain IC chips)

\section*{Protection against DPA}
- Reduce the signal
- Represent the data without hamming weight difference
e.g. \(0 \rightarrow 01,1 \rightarrow 1\)

Circuit size is increased
- Increase the noise
- Add the noise generator circuit
- Protection is deactivated by increasing the number of the power consumption data
- Duplicate the data
- Duplicate the intermediate data M into two random data \(\mathrm{M}_{1}\) and \(\mathrm{M}_{2}\)
satisfying \(\mathrm{M}=\mathrm{M}_{1} \oplus \mathrm{M}_{2}\)
- Processing time/circuit size is increased
- Update date the cryptographic key with certain period
- If the key before is updated enough number of the power consumption data is collected, the attack is avoided

Wireless Communication Engineering 1

\section*{Power analysis}

- Reveal the cryptographic key stored in the smart card by observing the power consumption(Kocher, 1998)
- Power consumption shows internal operation and data value in the smart card, which are related with the key
- Simple and powerful attack
- Just add a resistor to Vcc of IC chip
- Instrument is low-cost (Digital oscilloscope)

\footnotetext{
This attack is possible even when the implemented cryptographic algorithm is mathematically secure
}
